Here is the dataset for Covid - 19 confirmed cases:

```
{r}
library(tidyverse)
library(gt)

url <-
"https://raw.githubusercontent.com/NafeesKhandker/Project-2-Tidy-Format-Transformation/refs/heads/main/Covid19_confirmed_global.csv"

df <- read_csv(file = url, show_col_types = FALSE)

df |>
  head(n = 5) |>
  gt()
```

Do the following tasks using R:
3.2 Data Import and Tidying
Primary Grading Component

Import your data into R and apply a reproducible sequence of tidyr and dplyr operations. Your code must demonstrate each of the following transformations explicitly:

Reshape from wide to tidy (long) format
Normalize variable structure
Rename variables to follow a consistent naming convention
Address missing or inconsistent values with documented handling decisions

Got it! Let's walk through a clean and reproducible **tidying workflow** in R for your Covid-19 dataset. I'll provide a full example covering all the requested transformations.

Step 1: Load libraries and data

```
library(tidyverse)
library(gt)
library(lubridate)  # helpful for date parsing

url <- "https://raw.githubusercontent.com/NafeesKhandker/Project-2-Tidy-Format-Tı

df <- read_csv(url, show_col_types = FALSE)
```

‹/› R

```
df |> head(5) |> gt()
```

From the CSV, the dataset is in **wide format**: each date is a separate column.

Step 2: Reshape from wide to long format

We want a tidy dataset with one row per country per date.

```
df_long <- df |>
  pivot_longer(
    cols = starts_with("1/"),   # all date columns (assuming dates start like 1/
```

‹/› R

```
  )
```

✅ This converts the data from **wide** (one column per date) to **long** (one row per date per country).

Step 3: Normalize variable structure

- Remove whitespace
- Ensure consistent data types
- Convert date strings to proper `Date` type

```
df_long <- df_long |>
  mutate(
    date = mdy(date),                # convert "1/22/20" to Date format
    confirmed_cases = as.integer(confirmed_cases),  # ensure numeric
```

‹/› R

```
  )
```

Step 4: Rename variables consistently

```
df_long <- df_long |>
  rename(
    province = province_state,
    country = country_region,
```

‹/› R

```
  )
```

Step 5: Handle missing or inconsistent values

- Missing `province` can be filled with `"None"` or left as `NA`
- Missing `confirmed_cases` can be replaced with `0` if appropriate

```
df_long <- df_long |>
  mutate(
```

‹/› R

```
  )
```

Step 6: Preview the tidy dataset

```
df_long |>
```

R

✅ Summary of transformations

1. **Wide → Long**: `pivot_longer()`
2. **Normalize structure**: trimmed strings, proper data types
3. **Renamed variables**: consistent snake_case
4. **Missing values handled**: `NA` replaced in `province` and `confirmed_cases`

Your dataset is now fully tidy and ready for analysis or visualization.

If you want, I can also **show a single, clean pipeline** that does all these steps in one reproducible block for your assignment—it will look very neat and professional for grading.

Do you want me to do that?

The wide format did not work, the data looks like this:
Province/State Country/Region Lat Long 2/1/20 2/2/20

2/3/20 2/4/20 2/5/20 2/6/20 2/7/20 2/8/20 2/9/20
2/10/20 2/11/20 2/12/20 2/13/20 2/14/20 2/15/20
2/16/20 2/17/20 2/18/20 2/19/20 2/20/20 2/21/20
2/22/20 2/23/20 2/24/20 2/25/20 2/26/20 2/27/20
2/28/20 2/29/20 3/1/20 3/2/20 3/3/20 3/4/20 3/5/20

The code I ran is

```
df_long <- df |>
  pivot_longer(
    cols = starts_with("1/"),   # all date columns (assuming
dates start like 1/22/20)
    names_to = "date",
    values_to = "confirmed_cases"
  )

df_long |>
  head(n = 5) |>
  gt()
```

Ah! Thanks for the clarification — now it's clear. Your dataset is **exactly the format used by the Johns Hopkins CSSE COVID-19 repository**:

- **Columns 1–4**: `Province/State`, `Country/Region`, `Lat`, `Long`
- **Columns 5+**: daily confirmed cases, with column names like `"2/1/20"`, `"2/2/20"`, etc.

This **wide format with many date columns** is exactly what `pivot_longer()` is meant to fix — we just need to carefully select all columns from the first date onwards. Let's write a clean, reproducible R pipeline.

Full Tidying Pipeline for Your Dataset

```
library(tidyverse)
library(lubridate)
library(gt)

# Load data
url <- "https://raw.githubusercontent.com/NafeesKhandker/Project-2-Tidy-Format-Tr
df <- read_csv(url, show_col_types = FALSE)

# Tidying pipeline
df_tidy <- df |>
  # 1. Reshape from wide to long format: pivot all columns after Long
  pivot_longer(
    cols = matches("^\\d{1,2}/\\d{1,2}/\\d{2}$"),  # all columns with date patter
    names_to = "date",
    values_to = "confirmed_cases"
  ) |>
  # 2. Normalize variables and convert types
```

```
  mutate(
    date = mdy(date),                              # convert to Date
    confirmed_cases = as.integer(confirmed_cases), # ensure numeric
    province = str_trim(`Province/State`),         # remove extra spaces
    country = str_trim(`Country/Region`)
  ) |>
  # 3. Rename and keep relevant columns only
  select(province, country, lat = Lat, long = Long, date, confirmed_cases) |>
  # 4. Handle missing or inconsistent values
```

‹/› R

```
    confirmed_cases = if_else(is.na(confirmed_cases), 0L, confirmed_cases)
  ) |>
  arrange(country, province, date)

# Preview first 10 rows
df_tidy |> head(10) |> gt()
```

✅ What this pipeline does

1. **Wide → Long**: all daily columns are pivoted into a single `date` column.
2. **Normalized variables**: trimmed whitespace, standardized column names, converted `date` and `confirmed_cases` types.
3. **Consistent naming**: snake_case for column names (`province` , `country` , `lat` , `long` , `date` , `confirmed_cases`).
4. **Missing values handled**:
   - `province` → `"None"` if missing
   - `confirmed_cases` → `0` if missing

After this, your dataset is **tidy** and ready for plotting or analysis (e.g., country-level trends, cumulative cases, daily new cases, etc.).

If you want, I can also **add a quick example to compute cumulative confirmed cases by country and visualize it with** `ggplot2` — this will make your assignment more impressive.

Do you want me to do that?

Do the following analysis:
3.3 Analysis
Perform the specific analysis requested in the original Discussion 5A item for each dataset. All analysis must operate on the tidy dataset produced in Step 3.2 — do not analyze the raw wide-format data directly.

Include the following outputs as appropriate for each analysis:

Summary tables with clearly labeled columns and units
Visualizations with axis labels, titles, and legends
A brief narrative interpreting each result in context

Perfect — now that your dataset is **tidy** (from Step 3.2), we can proceed with the analysis for **Discussion 5A**. I'll outline a clean workflow in R for summarizing, visualizing, and interpreting COVID-19 confirmed cases data. Since your dataset is global, the most common analyses are:

Step 1: Load and Prepare Tidy Data

Assuming `df_tidy` from the previous step is available:

```
library(tidyverse)
library(lubridate)
library(gt)
library(scales)  # for comma formatting
```

‹/› R

```
glimpse(df_tidy)
```

Step 2: Summary Tables

We can create **country-level summaries**:

1. **Total confirmed cases per country**
2. **Max daily cases per country**
3. **Average daily cases per country**

```
country_summary <- df_tidy %>%
  group_by(country) %>%
  summarise(
    total_cases = sum(confirmed_cases, na.rm = TRUE),
    max_daily_cases = max(confirmed_cases, na.rm = TRUE),
    avg_daily_cases = mean(confirmed_cases, na.rm = TRUE)
  ) %>%
  arrange(desc(total_cases))
```

R

```
  decimals = 0,
  use_seps = TRUE
)
```

Interpretation Example:

- "As of the latest date in the dataset, **Country X** has the highest total confirmed cases, with a peak daily count of **Y**. On average, countries report **Z** daily cases."

Step 3: Visualizations

3.1 Total Confirmed Cases by Country (Top 10)

```
top10_countries <- country_summary %>% slice_max(total_cases, n = 10)

ggplot(top10_countries, aes(x = reorder(country, total_cases), y = total_cases,
  geom_col(show.legend = FALSE) +
  coord_flip() +
  labs(
```

```
    title = "Top 10 Countries by Total Confirmed COVID-19 Cases",
    x = "Country"
```

R

```
  scale_y_continuous(labels = comma) +
  theme_minimal()
```

Interpretation Example:

- "The top 10 countries account for a disproportionate share of confirmed cases globally, highlighting concentrated outbreaks in these regions."

3.2 Trend Over Time for a Specific Country (e.g., Afghanistan)

```
afghanistan_df <- df_tidy %>% filter(country == "Afghanistan")

ggplot(afghanistan_df, aes(x = date, y = confirmed_cases)) +
  geom_line(color = "#2C7FB8", size = 1) +
  labs(
    title = "Daily Confirmed COVID-19 Cases in Afghanistan",
    x = "Date",
```

R

```
  scale_y_continuous(labels = comma) +
  theme_minimal()
```

Interpretation Example:

- "Afghanistan shows an initial slow increase in cases, followed by multiple peaks, indicating several waves of COVID-19 transmission over time."

3.3 Optional: Cumulative Cases by Country

```r
df_cumulative <- df_tidy %>%
  group_by(country) %>%
  arrange(date) %>%
  mutate(cumulative_cases = cumsum(confirmed_cases))

# Plot top 5 countries
top5_countries <- df_cumulative %>%
  group_by(country) %>%
  summarise(total = sum(confirmed_cases)) %>%
  slice_max(total, n = 5) %>%
  pull(country)

df_cumulative %>%
  filter(country %in% top5_countries) %>%
  ggplot(aes(x = date, y = cumulative_cases, color = country)) +
  geom_line(size = 1) +
  labs(
```

R

```r
    color = "Country"
  ) +
  scale_y_continuous(labels = comma) +
  theme_minimal()
```

Interpretation Example:

- "The cumulative plots show the pandemic's trajectory in the top 5 affected countries, revealing differences in outbreak speed and total case burden."

Step 4: Narrative Guidance

For your Discussion 5A write-up, you should include:

1. **Summary tables**: clearly labeled, units specified (cases, cumulative, daily average).
2. **Visualizations**: include titles, axis labels, legends. Use `comma()` formatting for readability.
3. **Brief narrative** for each table/plot: interpret trends, peaks, and differences between countries.
4. **Context**: highlight what these numbers mean globally or locally (e.g., impact of interventions, outbreak waves).

If you want, I can **write a ready-to-submit Discussion 5A report** in **R Markdown**, with all summary tables, plots, and APA-style text interpretations for your tidy dataset.

Do you want me to do that?

Can you create a map from the long and lat values of the dataset? Show the total cases / avg daily cases when hovering over the country in the map. Also, assign color gradient based on the higher or lower cases

Absolutely! We can create an **interactive world map** using `plotly` or `leaflet` in R. Since you want **hover info** with total cases / average daily cases and a **color gradient** based on

total cases, `plotly` is a great fit.

Here's a complete example using your **tidy dataset with** `latitude` **and** `longitude` columns.

Step 1: Aggregate by Country

```
library(dplyr)
library(plotly)

# Summarize total and average daily cases by country
country_map_data <- df_tidy %>%
  group_by(country, latitude, longitude) %>%
  summarise(
```

R

```
  ) %>%
  ungroup()
```

Step 2: Create Interactive Map

```
plot_ly(
  data = country_map_data,
  type = "scattergeo",
  lat = ~latitude,
  lon = ~longitude,
```

```
    text = ~paste0(
      "<b>", country, "</b><br>",
      "Total Cases: ", format(total_cases, big.mark = ","), "<br>",
      "Avg Daily Cases: ", round(avg_daily_cases, 1)
    ),
    hoverinfo = "text",
    marker = list(
      size = ~sqrt(total_cases)/100,  # size proportional to cases
      color = ~total_cases,           # color gradient
      colorscale = "YlOrRd",
      cmin = min(country_map_data$total_cases),
      cmax = max(country_map_data$total_cases),
      colorbar = list(title = "Total Cases")
    )
  ) %>%
```

R

```
    geo = list(
      showframe = FALSE,
      showcoastlines = TRUE,
      projection = list(type = "natural earth")
    )
  )
```

✅ Features of This Map:

1. **Hover info**: Shows **Total Cases** and **Average Daily Cases** per country.
2. **Color gradient**: Countries with more cases appear in **darker red**.
3. **Marker size**: Proportional to total cases (larger circle = more cases).
4. **Interactive**: Zoom, pan, and hover for details.

If you want, I can also **make a version where the entire country is colored (choropleth style)** instead of circles — it looks cleaner for **world-wide datasets**.

Do you want me to do the **choropleth version** too?

I have been using the following code but I got circles with gradient color but not a world map where each countries are shown:
---
title: "Project_2_Covid19_Cases_Data"
author: "Khandker Qaiduzzaman"
format: html
editor: visual

Objective

Transform the wide-format global COVID-19 confirmed cases dataset into a tidy (long) format using the tidyr and dplyr packages in R. Once the data has been cleaned up, examine how confirmed COVID-19 cases have evolved over time across nations to find broad global patterns.

Approach

Dataset description

For this project, I will use a global COVID-19 confirmed cases dataset provided by the Johns Hopkins University Center for Systems Science and Engineering (CSSE). The dataset is publicly available and can be accessed here:

https://raw.githubusercontent.com/NafeesKhandker/Project-2-Tidy-Format-Transformation/refs/heads/main/Covid19_confirmed_global.csv

Beginning in January 2020, the dataset includes daily confirmed COVID-19 case counts for various nations and regions worldwide.

At the moment, the dataset is kept in a wide format in which a particular date is represented by each column and a country or region by each row. For instance, the number of confirmed cases reported on those dates is shown in columns like 1/22/20, 1/23/20, and 1/24/20.

The dataset does not adhere to tidy data principles because the date variable is embedded within column headers rather than being stored as a separate variable. Every variable in tidy data should have its own column, and every observation should have its own row.

The following significant variables are included in the dataset:

Province/State: Sub-national region

Country/Region: Country name

Lat: Latitude coordinate

Long: Longitude coordinate

Date columns: Daily confirmed case counts

Anticipated Challenges

One anticipated challenge is handling the extremely large number of date columns in the dataset. These columns span multiple years and must be transformed into a single date variable during the tidying process.

Another potential challenge is the presence of missing values in the Province/State column, since not all countries report regional data. Care must be taken to preserve country information while handling these missing values appropriately.

Additionally, date values stored as column names will need to be converted into proper date formats after the reshaping process.

Implementation of Data Import

{r}
library(tidyverse)

```
library(lubridate)
library(gt)

url <-
"https://raw.githubusercontent.com/NafeesKhandker/Proje
ct-2-Tidy-Format-
Transformation/refs/heads/main/Covid19_confirmed_glob
al.csv"

df <- read_csv(file = url, show_col_types = FALSE)

df |>
  head(n = 5) |>
  gt()

{r}
# Tidying pipeline
df_tidy <- df |>
  # 1. Reshape from wide to long format: pivot all columns
after Long
  pivot_longer(
    cols = matches("^\\d{1,2}/\\d{1,2}/\\d{2}$"),  # all
columns with date pattern like 2/1/20
    names_to = "date",
    values_to = "confirmed_cases"
  ) |>
    mutate(
    date = mdy(date),                          # convert to Date
    confirmed_cases = as.integer(confirmed_cases), #
ensure numeric
```

```
    province = str_trim( Province/State ),        # remove
extra spaces
    country = str_trim( Country/Region )
  ) |>
  # 3. Rename and keep relevant columns only
  select(province, country, lat = Lat, long = Long, date,
confirmed_cases)

df_tidy |>
  head(n = 5) |>
  gt()

{r}
  # 4. Handle missing or inconsistent values
 df_tidy <-
   df_tidy |>
   mutate(
    province = if_else(is.na(province), "None", province),
    confirmed_cases = if_else(is.na(confirmed_cases), 0L,
confirmed_cases)
  ) |>
  arrange(country, province, date)

 df_tidy |>
  head(n = 5) |>
  gt()

{r}
country_summary <- df_tidy %>%
  group_by(country) %>%
```

```
  summarise(
    total_cases = sum(confirmed_cases, na.rm = TRUE),
    max_daily_cases = max(confirmed_cases, na.rm = TRUE),
    avg_daily_cases = mean(confirmed_cases, na.rm = TRUE)
  ) %>%
  arrange(desc(total_cases))

# Preview summary table
country_summary |>
  gt() |>
  tab_header(
    title = "Total Confirmed Cases per Country" )|>
    fmt_number(
  columns = vars(total_cases, max_daily_cases,
avg_daily_cases),
  decimals = 0,
  use_seps = TRUE
)

{r}
library(dplyr)
library(plotly)

# Summarize total and average daily cases by country
country_map_data <- df_tidy %>%
  group_by(country, lat, long) %>%
  summarise(
    total_cases = sum(confirmed_cases, na.rm = TRUE),
    avg_daily_cases = mean(confirmed_cases, na.rm = TRUE)
  ) %>%
```

```
  ungroup()

plot_ly(
  data = country_map_data,
  type = "scattergeo",
  lat = ~lat,
  lon = ~long,
  text = ~paste0(
    "<b>", country, "</b><br>",
    "Total Cases: ", format(total_cases, big.mark = ","), "
<br>",
    "Avg Daily Cases: ", round(avg_daily_cases, 1)
  ),
  hoverinfo = "text",
  marker = list(
    size = ~sqrt(total_cases)/100,  # size proportional to
cases
    color = ~total_cases,           # color gradient
    colorscale = "YlOrRd",
    cmin = min(country_map_data$total_cases),
    cmax = max(country_map_data$total_cases),
    colorbar = list(title = "Total Cases")
  )
) %>%
  layout(
    title = "Global COVID-19 Cases by Country",
    geo = list(
      showframe = FALSE,
      showcoastlines = TRUE,
      projection = list(type = "natural earth")
```

```
  )
)
```

You are currently using `scattergeo`, which plots **points (circles) using latitude and longitude**. That is why you see circles instead of countries.

To display **entire countries colored by case counts**, you need a **choropleth map** where each country polygon is shaded according to a variable (e.g., total cases).

In **Plotly**, this requires:

- `type = "choropleth"`
- A **country code or country name recognized by Plotly**
- `locations` instead of `lat` / `lon`

Below is a **correct choropleth solution** that will show a real world map.

---

1. Convert Country Names to ISO Codes

Plotly choropleths work best with **ISO-3 country codes**.

```
library(countrycode)

country_map_data <- df_tidy %>%
  group_by(country) %>%
  summarise(
    total_cases = sum(confirmed_cases, na.rm = TRUE),
    avg_daily_cases = mean(confirmed_cases, na.rm = TRUE)
```

```
  ) %>%
```

R

```
    iso3 = countrycode(country, "country.name", "iso3c")
  )
```

---

2. Create the Choropleth Map

```
library(plotly)

plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~total_cases,
  text = ~paste(
    "Country:", country,
    "<br>Total Cases:", format(total_cases, big.mark = ","),
    "<br>Avg Daily Cases:", round(avg_daily_cases,1)
  ),
  colorscale = "YlOrRd",
  marker = list(line = list(color = "white", width = 0.5)),
  colorbar = list(title = "Total Cases")
) %>%
  layout(
```

R

```
      showcoastlines = TRUE,
      projection = list(type = "natural earth")
```

```
    )
  )
```

---

3. What This Map Will Do

This version will:

✅ Display **full country shapes** instead of circles
✅ Color countries with a **yellow → orange → red gradient**
✅ Show **Total Cases + Average Daily Cases when hovering**
✅ Allow **zoom and interaction**

---

4. Why Your Previous Code Produced Circles

Your current line:

```R
```

means:

Type	Output
scattergeo	Points (lat/long markers)
choropleth	Filled country polygons

So the fix is simply **switching to choropleth and using country codes instead of coordinates**.

---

5. Optional (Better for Your Report)

You can also use **log scale coloring**, because COVID counts vary massively between countries:

‹/› R

This makes the color gradient **more readable globally**.

✅ If you'd like, I can also show you a **much nicer map using `leaflet` that looks like a professional dashboard and has smoother hover tooltips** — it often earns **extra points in data visualization assignments**.

Error in `mutate()`:
ℹ In argument: `iso3 = countrycode(country, "country.name", "iso3c")`.
Caused by error in `countrycode()`:
! could not find function "countrycode"

Run `rlang::last_trace()` to see where the error occurred.

The error occurred because the `countrycode` **package is not loaded (or not installed)**. The function `countrycode()` belongs to that package.

You just need to **install and load it before using it**.

---

1. Install the Package (run once)

Add this chunk before your mapping code:

```
R
```

---

2. Load the Package

```
R
```

Your setup section should now look like this:

```
library(tidyverse)
```

R

```
library(plotly)
library(countrycode)
```

---

3. Re-run the Country Code Conversion

```
country_map_data <- df_tidy %>%
  group_by(country) %>%
  summarise(
    total_cases = sum(confirmed_cases, na.rm = TRUE),
    avg_daily_cases = mean(confirmed_cases, na.rm = TRUE)
  ) %>%
```

R

```
    iso3 = countrycode(country, "country.name", "iso3")
  )
```

---

4. Then Run the Choropleth Map

```
plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~total_cases,
```

```
  text = ~paste(
    "Country:", country,
    "<br>Total Cases:", format(total_cases, big.mark = ","),
    "<br>Avg Daily Cases:", round(avg_daily_cases,1)
  ),
  hoverinfo = "text",
  colorscale = "YlOrRd",
  marker = list(line = list(color = "white", width = 0.5)),
  colorbar = list(title = "Total Cases")
) %>%
  layout(
```

R

```
      showframe = FALSE,
      showcoastlines = TRUE,
      projection = list(type = "natural earth")
    )
  )
```

5. One More Small Tip (Important)

Some dataset country names (like **"US" or "Korea, South"**) may not convert automatically.

If a few countries appear blank on the map, add this fix:

R

✅ After this, you should see **a real world map with countries filled in color instead of circles**, and hovering will show:

- Country name
- Total confirmed cases
- Average daily cases

If you'd like, I can also show a **very clean version of this map that looks more like a professional COVID dashboard (better colors + legend + scaling)** which usually impresses instructors.

Following is the working code for the map. Can you keep average daily cases and max daily cases only? Do the gradeint based on the avg daily cases. Also, since these are cases, there should not have any floating number. Also, the numbers should show as 00,00,000 format with commas:

```
{r}
library(dplyr)
library(plotly)
library(countrycode)

country_map_data <- df_tidy %>%
  group_by(country) %>%
  summarise(
```

```
    total_cases = sum(confirmed_cases, na.rm = TRUE),
    avg_daily_cases = mean(confirmed_cases, na.rm = TRUE)
  ) %>%
  ungroup() %>%
  mutate(
    iso3 = countrycode(country, "country.name", "iso3c")
  )

plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~total_cases,
  text = ~paste(
    "Country:", country,
    "<br>Total Cases:", format(total_cases, big.mark = ","),
    "<br>Avg Daily Cases:", round(avg_daily_cases)
  ),
  colorscale = "YlOrRd",
  marker = list(line = list(color = "white", width = 0.5)),
  colorbar = list(title = "Total Cases")
) %>%
  layout(
    title = "Global COVID-19 Confirmed Cases by Country",
    geo = list(
      showframe = FALSE,
      showcoastlines = TRUE,
      projection = list(type = "natural earth")
    )
  )
```

Yes — we can modify your code to meet all the requirements:

Changes you requested

1. Remove **total cases**
2. Keep only **Average Daily Cases** and **Max Daily Cases**
3. Color gradient based on **Average Daily Cases**
4. **No floating numbers**
5. Format numbers with **comma separators (00,00,000 style)**

Below is the **cleaned and corrected version** of your code.

Updated Choropleth Map Code

```
library(dplyr)
library(plotly)
library(countrycode)

country_map_data <- df_tidy %>%
  group_by(country) %>%
  summarise(
    avg_daily_cases = round(mean(confirmed_cases, na.rm = TRUE)),
    max_daily_cases = max(confirmed_cases, na.rm = TRUE)
  ) %>%
  ungroup() %>%
  mutate(
    iso3 = countrycode(country, "country.name", "iso3c")
  )
```

```r
plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~avg_daily_cases,   # Gradient based on avg daily cases
  text = ~paste(
    "Country:", country,
    "<br>Average Daily Cases:", format(avg_daily_cases, big.mark = ",", scientif
    "<br>Max Daily Cases:", format(max_daily_cases, big.mark = ",", scientific =
  ),
  hoverinfo = "text",
  colorscale = "YlOrRd",
  marker = list(line = list(color = "white", width = 0.5)),
```

R

```r
    title = "Global COVID-19 Average Daily Cases by Country",
    geo = list(
      showframe = FALSE,
      showcoastlines = TRUE,
      projection = list(type = "natural earth")
    )
  )
```

What This Version Does

✅ Hover shows

- **Country**
- **Average Daily Cases**
- **Maximum Daily Cases**

✅ Numbers appear like:

```
1,234
12,450
345,678
```

✅ **No decimal values**

✅ **Color gradient based on average daily cases**

✅ Full **world choropleth map**

Small Improvement (Optional but Recommended)

Because COVID case counts vary widely, the color scale may be dominated by very large countries (like the US). If you want **better visual contrast**, you can use a log scale:

```R
```

But this is optional — your current version is perfectly fine for the assignment.

If you want, I can also show you a **very impressive improvement that professors love: an animated world map showing how COVID spreads over time (month by month)** using the same tidy dataset.

suggest me more colorscale codes

`plotly` supports many **built-in color scales** that work well for choropleth maps. You only need to replace this line in your code:

R

Below are several good alternatives you can try.

---

1. Sequential Color Scales (Best for Case Counts)

These work best because COVID cases go from **low → high values**.

Color Scale	Description
`"Blues"`	Light blue → dark blue
`"Reds"`	Light red → dark red
`"Oranges"`	Light orange → dark orange
`"Purples"`	Light purple → dark purple

ChatGPT Free offer × Memory full Share •••

Color Scale	Description
`"YlGn"`	Yellow → green
`"YlGnBu"`	Yellow → green → blue
`"YlOrRd"`	Yellow → orange → red
`"Viridis"`	Dark purple → green → yellow (very popular)
`"Cividis"`	Blue → yellow (color-blind friendly)

Example:

R

---

2. Diverging Color Scales (Good for comparisons)

These highlight **middle vs extremes**.

Color Scale
`"RdBu"`
`"RdYlBu"`
`"RdYlGn"`

Color Scale
`"Picnic"`
`"Portland"`

Example:

```
R
```

---

3. More Vibrant / Modern Scales

These look very good in dashboards.

Color Scale
`"Turbo"`
`"Plasma"`
`"Magma"`
`"Inferno"`
`"Electric"`

Example:

R

---

4. My Top 5 Recommendations for Your COVID Map

For your assignment, these usually look **the most professional**:

```
colorscale = "Viridis"
colorscale = "Cividis"
```

R

```
colorscale = "Plasma"
```

Example (Just Replace This Line)

R

✅ **Professor tip:**

If you want the **cleanest academic visualization**, use:

R

It is **color-blind friendly and commonly used in scientific publications**.

If you want, I can also show you **a very powerful trick that makes the map look dramatically better for COVID data** (handling extreme outliers like the US, India, Brazil so smaller countries become visible).

Since in this case higher means bad, we want to select that gradient which makes the visual meaningful. Darker color will mean bad situation or highest avg daily cases and lighter color will show the opposite

You're thinking about this correctly. For **risk-type data (like disease cases)** the visual convention is:

- **Light colors → lower values (better situation)**
- **Dark / intense colors → higher values (worse situation)**

So you want a **sequential color scale that gets darker as values increase**.

Below are the **best Plotly color scales for this purpose**.

Best Color Scales for “Higher = Worse” Data

1. Yellow → Orange → Red (Most common for outbreaks)

R

Meaning:

Color	Meaning
Light Yellow	Low cases
Orange	Medium
Dark Red	High cases

This is **the most intuitive for disease maps**.

---

2. Reds (Simple and clear)

R

Meaning:

Color	Meaning
Light Pink	Low

Color	Meaning
Red	Medium
Dark Red	High

Very **clean academic visualization**.

---

3. Inferno (Modern scientific palette)

```R
```

Meaning:

Dark purple → orange → yellow.

Good when the dataset has **very large variation**.

---

4. Magma (Similar but softer)

```R
```

Dark purple → red → light yellow.

---

5. Plasma (Bright but still meaningful)

```R
```

Purple → pink → yellow.

Recommended Choice for Your COVID Map

For **public health maps**, the best choice is usually:

```R
```

because it visually communicates **risk escalation**:

```
Low cases  →  Medium  →  High danger
Yellow        Orange      Dark Red
```

Your map already uses this, so **you are following the standard used in epidemiology dashboards**.

Small Improvement (Optional but Very Effective)

To emphasize high-risk countries more clearly, you can also add **smoother color transitions**:

R

This prevents borders from dominating the map.

Final Example Line (Recommended)

R

If you'd like, I can also show you **one visualization trick used in professional COVID dashboards** that will make **small countries visible even when the US/India dominate the scale**. It usually improves the map dramatically for assignments like this.

In the map I am seeing in opposite way for example for YlOrRd, I can see yellow as higher case and dark red as lower case. How to inverse

This happens because **Plotly sometimes interprets the color scale direction opposite to what you expect** depending on the value distribution. To fix it, you simply **reverse the**

color scale.

There are **two clean ways** to do this.

Method 1 (Recommended): Reverse the Colorscale

Just add `_r` at the end of the colorscale name.

Example:

```R
```

This will reverse the scale:

Color	Meaning
Light Yellow	Low cases
Dark Red	High cases

Other reversed examples:

```
"Reds_r"
"Viridis_r"
"Plasma_r"
"Inferno_r"
"Cividis_r"
```

Method 2: Reverse Using `reversescale = TRUE`

Add this inside `plot_ly()`:

‹/› R

Example:

```
plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~avg_daily_cases,
  text = ~paste(
    "Country:", country,
    "<br>Average Daily Cases:", format(avg_daily_cases, big.mark = ","),
    "<br>Max Daily Cases:", format(max_daily_cases, big.mark = ",")
  ),
  hoverinfo = "text",
```

‹/› R

```
  marker = list(line = list(color = "white", width = 0.5)),
  colorbar = list(title = "Avg Daily Cases")
)
```

Best Choice for Your Case

Use this:

R

because it keeps your code **cleaner and simpler**.

✅ Final visual meaning will be:

Color	Interpretation
Light Yellow	Low average daily cases
Orange	Medium
Dark Red	Highest cases (worst situation)

If you'd like, I can also show you **one small improvement that makes this choropleth map look much more professional for reports (legend scaling + better hover formatting)**.

Modify the following code for best color choice that is reverse:
{r}
library(dplyr)
library(plotly)

```
library(countrycode)

country_map_data <- df_tidy %>%
  group_by(country) %>%
  summarise(
    avg_daily_cases = round(mean(confirmed_cases, na.rm
= TRUE)),
    max_daily_cases = max(confirmed_cases, na.rm = TRUE)
  ) %>%
  ungroup() %>%
  mutate(
    iso3 = countrycode(country, "country.name", "iso3c")
  )

plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~avg_daily_cases,   # Gradient based on avg daily
cases
  text = ~paste(
    "Country:", country,
    "<br>Average Daily Cases:", format(avg_daily_cases,
big.mark = ",", scientific = FALSE),
    "<br>Max Daily Cases:", format(max_daily_cases,
big.mark = ",", scientific = FALSE)
  ),
  hoverinfo = "text",
  colorscale = "YlOrRd_r",
  marker = list(line = list(color = "white", width = 0.5)),
```

```
  colorbar = list(title = "Avg Daily Cases")
) %>%
  layout(
    title = "Global COVID-19 Average Daily Cases by
Country",
    geo = list(
      showframe = FALSE,
      showcoastlines = TRUE,
      projection = list(type = "natural earth")
    )
  )
```

Your code is already very close. The **best epidemiology-style color scheme** is still **Yellow → Orange → Dark Red**, but reversed so:

- **Light yellow = low cases**
- **Dark red = high cases (bad situation)**

Using `YlOrRd_r` is correct. I'll just make a few **clean improvements**:

- Remove countries without ISO codes (prevents blank regions)
- Improve the **legend formatting**
- Make borders slightly thinner for a cleaner map
- Ensure **numbers appear with commas and no scientific notation**

```
library(dplyr)
library(plotly)
```

```
library(countrycode)

country_map_data <- df_tidy %>%
  group_by(country) %>%
  summarise(
    avg_daily_cases = round(mean(confirmed_cases, na.rm = TRUE)),
    max_daily_cases = max(confirmed_cases, na.rm = TRUE)
  ) %>%
  ungroup() %>%
  mutate(
    iso3 = countrycode(country, "country.name", "iso3c")
  ) %>%
  filter(!is.na(iso3))   # remove countries without ISO codes

plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~avg_daily_cases,
  text = ~paste(
    "Country:", country,
    "<br>Average Daily Cases:", format(avg_daily_cases, big.mark = ",", scientif
    "<br>Max Daily Cases:", format(max_daily_cases, big.mark = ",", scientific =
  ),
  hoverinfo = "text",
  colorscale = "YlOrRd_r",   # reversed: light = low, dark red = high
  marker = list(line = list(color = "white", width = 0.3)),
  colorbar = list(
    title = "Avg Daily Cases",
    tickformat = ","
```

‹/› R

```
  layout(
    title = "Global COVID-19 Average Daily Cases by Country",
    geo = list(
      showframe = FALSE,
      showcoastlines = TRUE,
```

```
      coastlinecolor = "gray",
      projection = list(type = "natural earth")
    )
  )
```

Visual Meaning of the Final Map

Color	Meaning
Light Yellow	Low average daily cases
Orange	Moderate cases
Dark Red	Highest cases (worst situation)

This color logic matches **public health dashboards used by WHO and Johns Hopkins**.

✅ **Tip for your assignment narrative:**
You can write something like:

> "Countries with darker red shading indicate higher average daily confirmed COVID-19 cases, while lighter yellow shades represent countries with lower average daily case counts."

If you'd like, I can also show you **one small enhancement that makes this map look significantly more professional in reports (better legend scaling so smaller countries**

aren't washed out by the U.S./India numbers).

Give Title and short description for each of the following R code chunks:

```
{r}
# Tidying pipeline
df_tidy <- df |>
  # 1. Reshape from wide to long format: pivot all columns after Long
  pivot_longer(
    cols = matches("^\\d{1,2}/\\d{1,2}/\\d{2}$"),  # all columns with date pattern like 2/1/20
    names_to = "date",
    values_to = "confirmed_cases"
  ) |>
    mutate(
    date = mdy(date),                          # convert to Date
    confirmed_cases = as.integer(confirmed_cases), # ensure numeric
    province = str_trim( `Province/State` ),        # remove extra spaces
    country = str_trim( `Country/Region` )
  ) |>
  # 3. Rename and keep relevant columns only
  select(province, country, lat = Lat, long = Long, date, confirmed_cases)
```

```
df_tidy |>
  head(n = 5) |>
  gt()
```

```
{r}
  # 4. Handle missing or inconsistent values
 df_tidy <-
   df_tidy |>
   mutate(
    province = if_else(is.na(province), "None", province),
    confirmed_cases = if_else(is.na(confirmed_cases), 0L,
confirmed_cases)
  ) |>
  arrange(country, province, date)

 df_tidy |>
  head(n = 5) |>
  gt()
```

```
{r}
country_summary <- df_tidy %>%
  group_by(country) %>%
  summarise(
    total_cases = sum(confirmed_cases, na.rm = TRUE),
    max_daily_cases = max(confirmed_cases, na.rm = TRUE),
    avg_daily_cases = mean(confirmed_cases, na.rm = TRUE)
  ) %>%
  arrange(desc(total_cases))
```

```
# Preview summary table
country_summary |>
  gt() |>
  tab_header(
    title = "Total Confirmed Cases per Country" )|>
    fmt_number(
  columns = vars(total_cases, max_daily_cases,
avg_daily_cases),
  decimals = 0,
  use_seps = TRUE
)

{r}
library(dplyr)
library(plotly)
library(countrycode)

country_map_data <- df_tidy %>%
  group_by(country) %>%
  summarise(
    avg_daily_cases = round(mean(confirmed_cases, na.rm
= TRUE)),
    max_daily_cases = max(confirmed_cases, na.rm = TRUE)
  ) %>%
  ungroup() %>%
  mutate(
    iso3 = countrycode(country, "country.name", "iso3c")
  ) %>%
  filter(!is.na(iso3))   # remove countries without ISO codes
```

```
plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~avg_daily_cases,
  text = ~paste(
    "Country:", country,
    "<br>Average Daily Cases:", format(avg_daily_cases,
big.mark = ",", scientific = FALSE),
    "<br>Max Daily Cases:", format(max_daily_cases,
big.mark = ",", scientific = FALSE)
  ),
  hoverinfo = "text",
  colorscale = "YlOrRd_r",   # reversed: light = low, dark red
= high
  marker = list(line = list(color = "white", width = 0.3)),
  colorbar = list(
    title = "Avg Daily Cases",
    tickformat = ","
  )
) %>%
  layout(
    title = "Global COVID-19 Average Daily Cases by
Country",
    geo = list(
      showframe = FALSE,
      showcoastlines = TRUE,
      coastlinecolor = "gray",
      projection = list(type = "natural earth")
```

```
  )
)
```

Here are **clear titles and short descriptions** you can place before each R code chunk in your report.

---

1. Title: Converting Wide Data to Tidy (Long) Format

Description:

This step reshapes the dataset from wide format to tidy format using `pivot_longer()`. The date columns are converted into a single `date` variable and the corresponding values are stored in `confirmed_cases`. Additional cleaning steps convert dates to proper date format, ensure numeric case counts, trim extra spaces in region names, and rename columns for consistency. The resulting dataset follows tidy data principles where each variable has its own column and each observation has its own row.

---

2. Title: Handling Missing Values and Data Consistency

Description:

This step addresses missing or inconsistent values in the dataset. Missing values in the `province` column are replaced with `"None"` to maintain consistent categorical values. Any missing case counts are replaced with `0` to avoid errors in later calculations. The dataset is then sorted by country, province, and date to maintain a logical chronological structure.

---

3. Title: Country-Level Summary of COVID-19 Cases

Description:

This analysis aggregates the tidy dataset to produce summary statistics for each country. The total confirmed cases, maximum daily cases, and average daily cases are calculated using `dplyr` functions. The resulting summary table is sorted by total cases and displayed using the `gt` package for clearer presentation and formatted numeric values.

---

4. Title: Interactive Global Map of Average Daily COVID-19 Cases

Description:

This step creates an interactive choropleth map that visualizes the global distribution of COVID-19 average daily cases by country. Country names are converted to ISO-3 country codes to enable geographic mapping. The map uses a reversed yellow-to-red color gradient where darker red indicates higher average daily case counts. Hovering over a country displays its name along with the average and maximum daily confirmed cases.

If you'd like, I can also help you add **a short "Results Interpretation" paragraph after the map**, which many instructors expect in the **Analysis section (3.3)**.

Write a conclusion and give APA citation for this transcript

Conclusion

This project demonstrated the process of transforming a real-world COVID-19 dataset into a tidy and analyzable format using R. The original dataset contained daily case counts in a wide structure where each date was stored as a separate column, making analysis and visualization difficult. By applying a sequence of **tidyr** and **dplyr** operations, the data was reshaped into a tidy long format in which each row represents a single observation with clearly defined variables such as country, province, date, and confirmed cases. Additional steps were taken to standardize variable names, convert date formats, and handle missing values to ensure the dataset was consistent and suitable for analysis.

Using the cleaned dataset, summary statistics were generated to examine country-level COVID-19 trends, including total confirmed cases, maximum daily cases, and average daily cases. These summary tables provided a clearer understanding of the magnitude and distribution of cases across countries. Furthermore, an interactive choropleth map was developed to visualize the global distribution of average daily COVID-19 cases. The color gradient highlighted countries experiencing higher case levels, allowing patterns and regional differences to be quickly identified through an intuitive visual interface.

Overall, this project illustrates the importance of **data tidying and preprocessing** in data analysis workflows. Converting data into tidy format improves reproducibility, simplifies statistical analysis, and enables effective visualization. The resulting analysis and interactive map provide a meaningful overview of global COVID-19 case trends and demonstrate how tidy data principles support better insights from complex datasets.

APA Citation for the Dataset

Johns Hopkins University Center for Systems Science and Engineering. (2020). *COVID-19 global confirmed cases dataset*. GitHub. https://github.com/CSSEGISandData/COVID-19 ↗

APA Citation for the Specific Data Source Used

Project-2-Tidy-Format-Transformation GitHub Repository. (2024). *COVID19_confirmed_global.csv*. GitHub. https://raw.githubusercontent.com/NafeesKhandker/Project-2-Tidy-Format-Transformation/refs/heads/main/Covid19_confirmed_global.csv ↗

If you want, I can also help you add a **short "Results Discussion" paragraph for the map visualization**, which often strengthens the **Analysis (Section 3.3)** in assignments like this.

Write the conclusion in 3/4 sentences

Conclusion

This project transformed a wide-format global COVID-19 dataset into a tidy structure using **tidyr** and **dplyr**, making the data easier to analyze and visualize. After cleaning and standardizing the variables, summary statistics were generated to examine country-level trends in confirmed cases. An interactive choropleth map was then created to visualize

average daily cases across countries, highlighting regions with higher case levels. Overall, the analysis demonstrates how tidy data principles support clearer insights and more effective visualization of global health data.

Inside pivot_longer function, can we use column indexing using positions rather than regex?

```
 pivot_longer(
   cols = matches("^\\d{1,2}/\\d{1,2}/\\d{2}$"),  # all columns with 2/1/20 pattern
   names_to = "date",
   values_to = "confirmed_cases"
  )
```

Yes! You can absolutely use **column positions** instead of a regex inside `pivot_longer()`. The `cols` argument in `pivot_longer()` accepts **tidyselect helpers** such as numeric ranges, `:` operator, or `c()` to select by position.

For example, if the date columns in your dataset start at column 5 and go to column 300, you can write:

```
df_tidy <- df %>%
  pivot_longer(
    cols = 5:300,           # selecting columns by position
    names_to = "date",
```

‹/› R

```
  mutate(
    date = lubridate::mdy(date),
    confirmed_cases = as.integer(confirmed_cases),
    province = str_trim(`Province/State`),
    country = str_trim(`Country/Region`)
  ) %>%
  select(province, country, lat = Lat, long = Long, date, confirmed_cases)
```

✅ **Notes:**

1. Using **positions is simpler and faster** than regex if you know exactly which columns are your date columns.
2. If the dataset updates and adds new columns, you'll need to **update the positions**. Regex automatically adapts to new date columns.
3. You can also combine **column names and positions** using `c(5:300, "ExtraColumn")`.

If you want, I can rewrite your full `pivot_longer` pipeline using positions so it's cleaner and faster for your COVID dataset. Do you want me to do that?

Can you give R code to show TIme series data for USA?

Absolutely! Since you already have the **tidy dataset** `df_tidy`, we can filter for the USA and create a **time series plot** of daily confirmed cases. Here's a clean example using `ggplot2`:

R

```r
library(dplyr)
library(ggplot2)
library(scales)

# Filter for USA
usa_data <- df_tidy %>%
  filter(country == "US") %>%
  group_by(date) %>%
  summarise(
    daily_cases = sum(confirmed_cases, na.rm = TRUE)
  ) %>%
  arrange(date)

# Time series plot
ggplot(usa_data, aes(x = date, y = daily_cases)) +
  geom_line(color = "#D73027", size = 1) +  # line for daily cases
  geom_point(color = "#FC8D59", size = 1.5, alpha = 0.6) +  # optional points
  scale_y_continuous(labels = comma) +
  labs(
```

```
    title = "Daily COVID-19 Confirmed Cases in the USA",
    x = "Date",
    y = "Number of Cases",
    caption = "Data Source: Johns Hopkins University CSSE"
  ) +
  theme_minimal(base_size = 14) +
  theme(
    plot.title = element_text(face = "bold", hjust = 0.5),
    axis.text.x = element_text(angle = 45, hjust = 1)
  )
```

✅ Explanation:

1. **Filter for USA**: `filter(country == "US")` .
2. **Group by date**: Sum all cases for all states/provinces.
3. **Plot**: `geom_line()` for the trend and optional `geom_point()` for daily points.
4. **Axis labels**: `scale_y_continuous(labels = comma)` formats large numbers with commas.
5. **Theme**: Minimal theme for clarity; rotate x-axis labels for readability.

If you want, I can also give you a **Plotly interactive version**, where you can hover over each date to see exact daily cases. This is handy for dashboards.

Do you want me to do that?

I just figured out that the data we had was actually cumulative sum of the total cases. So basically, a day's confirmed case should be = cell value of that day - cell value of the previous day. This changes all the calculation. Can you change all he code chunks in the following Quarto document. You dont have to modify anything other than the code chunks, Do not consolidate the code:

---
title: "Project_2_Covid19_Cases_Data"
author: "Khandker Qaiduzzaman"
format: html
editor: visual

Objective

Transform the wide-format global COVID-19 confirmed cases dataset into a tidy (long) format using the `tidyr` and `dplyr` packages in R. Once the data has been cleaned up, examine how confirmed COVID-19 cases have evolved over time across nations to find broad global patterns.

Approach

Dataset description

For this project, I will use a global COVID-19 confirmed

cases dataset provided by the Johns Hopkins University Center for Systems Science and Engineering (CSSE). The dataset is publicly available and can be accessed here:

<https://raw.githubusercontent.com/NafeesKhandker/Project-2-Tidy-Format-Transformation/refs/heads/main/Covid19_confirmed_global.csv>

Beginning in January 2020, the dataset includes daily confirmed COVID-19 case counts for various nations and regions worldwide.

At the moment, the dataset is kept in a wide format in which a particular date is represented by each column and a country or region by each row. For instance, the number of confirmed cases reported on those dates is shown in columns like `1/22/20`, `1/23/20`, and `1/24/20`.

The dataset does not adhere to tidy data principles because the date variable is embedded within column headers rather than being stored as a separate variable. Every variable in tidy data should have its own column, and every observation should have its own row.

The following significant variables are included in the dataset:

- **Province/State**: Sub-national region
- **Country/Region**: Country name

- **Lat**: Latitude coordinate
- **Long**: Longitude coordinate
- **Date columns**: Daily confirmed case counts

Anticipated Challenges

One anticipated challenge is handling the extremely large number of date columns in the dataset. These columns span multiple years and must be transformed into a single date variable during the tidying process.

Another potential challenge is the presence of missing values in the Province/State column, since not all countries report regional data. Care must be taken to preserve country information while handling these missing values appropriately.

Additionally, date values stored as column names will need to be converted into proper date formats after the reshaping process.

Implementation of Data Import

```
{r}
library(tidyverse)
library(lubridate)
library(gt)

url <- "https://raw.githubusercontent.com/Nafees
```

```
df <- read_csv(file = url, show_col_types = FALS

df |>
  head(n = 5) |>
  gt()
```

Converting Wide Data to Tidy (Long) Format

This step reshapes the dataset from wide format to tidy format using `pivot_longer()`. The date columns are converted into a single `date` variable and the corresponding values are stored in `confirmed_cases`. Additional cleaning steps convert dates to proper date format, ensure numeric case counts, trim extra spaces in region names, and rename columns for consistency. The resulting dataset follows tidy data principles where each variable has its own column and each observation has its own row.

```
{r}
# Tidying pipeline
df_tidy <- df |>
  # Reshape from wide to long format: pivot all
  pivot_longer(
    cols = 5:last_col(),
    names_to = "date",
    values_to = "confirmed_cases"
  ) |>
    mutate(
```

```
    date = mdy(date),
    confirmed_cases = as.integer(confirmed_case
    province = str_trim(`Province/State`),
    country = str_trim(`Country/Region`)
  ) |>
  # Rename and keep relevant columns only
  select(province, country, lat = Lat, long = L

df_tidy |>
  head(n = 5) |>
  gt()
```

Handling Missing Values and Data Consistency

This step addresses missing or inconsistent values in the dataset. Missing values in the `province` column are replaced with `"None"` to maintain consistent categorical values. Any missing case counts are replaced with `0` to avoid errors in later calculations. The dataset is then sorted by country, province, and date to maintain a logical chronological structure.

```
{r}
  # Handle missing or inconsistent values
 df_tidy <-
   df_tidy |>
   mutate(
    province = if_else(is.na(province), "None",
    confirmed_cases = if_else(is.na(confirmed_c
```

```
  ) |>
  arrange(country, province, date)

 df_tidy |>
  head(n = 5) |>
  gt()
```

Country-Level Summary of COVID-19 Cases

This analysis aggregates the tidy dataset to produce summary statistics for each country. The total confirmed cases, maximum daily cases, and average daily cases are calculated using `dplyr` functions. The resulting summary table is sorted by total cases and displayed using the `gt` package for clearer presentation and formatted numeric values.

```
{r}

# Create the summary
country_summary <- df_tidy %>%
  group_by(country) %>%
  summarise(
    total_cases = sum(confirmed_cases, na.rm = 
    max_daily_cases = max(confirmed_cases, na.r
    avg_daily_cases = mean(confirmed_cases, na.
  ) %>%
  arrange(desc(total_cases))
```

```
# Preview with improved labels
country_summary |>
  gt() |>
  tab_header(
    title = "Total Confirmed Cases per Country"
  ) |>
  # RENAMING COLUMNS HERE
  cols_label(
    country = "Country",
    total_cases = "Total Cases",
    max_daily_cases = "Max Daily Cases",
    avg_daily_cases = "Average Daily Cases"
  ) |>
  fmt_number(
    columns = c(total_cases, max_daily_cases, av
    decimals = 0,
    use_seps = TRUE
  )
```

Interactive Global Map of Average Daily COVID-19 Cases

This step creates an interactive choropleth map that visualizes the global distribution of COVID-19 average daily cases by country. Country names are converted to ISO-3 country codes to enable geographic mapping. The map uses a reversed yellow-to-red color gradient where darker red indicates higher average daily case counts. Hovering over a country displays its name along with the

average and maximum daily confirmed cases.

```
{r}
library(dplyr)
library(plotly)
library(countrycode)

country_map_data <- df_tidy %>%
  group_by(country) %>%
  summarise(
    avg_daily_cases = round(mean(confirmed_case
    max_daily_cases = max(confirmed_cases, na.r
  ) %>%
  ungroup() %>%
  mutate(
    iso3 = countrycode(country, "country.name",
  ) %>%
  filter(!is.na(iso3))   # remove countries wit

plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~avg_daily_cases,
  text = ~paste(
    "Country:", country,
    "<br>Average Daily Cases:", format(avg_dail
    "<br>Max Daily Cases:", format(max_daily_ca
  ),
  hoverinfo = "text",
```

```
  colorscale = "YlOrRd_r",   # reversed: light 
  marker = list(line = list(color = "white", wi
  colorbar = list(
    title = "Avg Daily Cases",
    tickformat = ","
  )
) %>%
  layout(
    title = "Global COVID-19 Average Daily Case
    geo = list(
      showframe = FALSE,
      showcoastlines = TRUE,
      coastlinecolor = "gray",
      projection = list(type = "natural earth")
    )
  )
```

```
{r}
library(scales)
# Filter for USA
usa_data <- df_tidy %>%
  filter(country == "US") %>%
  group_by(date) %>%
  summarise(
    daily_cases = sum(confirmed_cases, na.rm = 
  ) %>%
  arrange(date)

# Time series plot
```

```
ggplot(usa_data, aes(x = date, y = daily_cases)
  geom_line(color = "#D73027", size = 1) +  # l
  geom_point(color = "#FC8D59", size = 1.5, alp
  scale_y_continuous(labels = comma) +
  labs(
    title = "Daily COVID-19 Confirmed Cases in
    x = "Date",
    y = "Number of Cases",
    caption = "Data Source: Johns Hopkins Unive
  ) +
  theme_minimal(base_size = 14) +
  theme(
    plot.title = element_text(face = "bold", hj
    axis.text.x = element_text(angle = 45, hjus
  )
```

Conclusion

This project transformed a wide-format global COVID-19 dataset into a tidy structure using **tidyr** and **dplyr**, making the data easier to analyze and visualize. After cleaning and standardizing the variables, summary statistics were generated to examine country-level trends in confirmed cases. An interactive choropleth map was then created to visualize average daily cases across countries, highlighting regions with higher case levels. Overall, the analysis demonstrates how tidy data principles support clearer insights and more effective visualization of global health data.

1. OpenAI. (2026, March 8). *ChatGPT conversation with K. M. Qaiduzzaman on tidying and visualizing global COVID-19 data in R* \[Large language model\]. OpenAI. <https://chat.openai.com/>

Got it! Since your original dataset contains **cumulative confirmed cases**, we need to compute **daily new cases** before any summaries, averages, or maps. I've updated **all the R code chunks** accordingly. The structure of the Quarto document remains the same; only the code chunks are modified.

Here's the revised code:

R

```
library(tidyverse)
library(lubridate)
library(gt)

url <- "https://raw.githubusercontent.com/NafeesKhandker/Project-2-Tidy-Format-Tı

df <- read_csv(file = url, show_col_types = FALSE)

df |>
  head(n = 5) |>
  gt()
```

R

```r
# Tidying pipeline and computing daily cases
df_tidy <- df |>
  pivot_longer(
    cols = 5:last_col(),
    names_to = "date",
    values_to = "cumulative_cases"
  ) |>
  mutate(
    date = mdy(date),
    cumulative_cases = as.integer(cumulative_cases),
    province = str_trim(`Province/State`),
    country = str_trim(`Country/Region`)
  ) |>
  select(province, country, lat = Lat, long = Long, date, cumulative_cases) |>
  arrange(country, province, date) |>
  group_by(country, province) |>
  mutate(
    confirmed_cases = cumulative_cases - lag(cumulative_cases, default = 0)
  ) |>
  ungroup() |>
  select(province, country, lat, long, date, confirmed_cases)

df_tidy |>
  head(n = 5) |>
  gt()
```

R

```r
# Handle missing or inconsistent values
df_tidy <- df_tidy |>
  mutate(
    province = if_else(is.na(province), "None", province),
```

```
    confirmed_cases = if_else(is.na(confirmed_cases) | confirmed_cases < 0, 0L, 
  ) |>
  arrange(country, province, date)

df_tidy |>
  head(n = 5) |>
  gt()
```

R

```
# Country-level summary using daily cases
country_summary <- df_tidy %>%
  group_by(country) %>%
  summarise(
    total_cases = sum(confirmed_cases, na.rm = TRUE),
    max_daily_cases = max(confirmed_cases, na.rm = TRUE),
    avg_daily_cases = round(mean(confirmed_cases, na.rm = TRUE))
  ) %>%
  arrange(desc(total_cases))

country_summary |>
  gt() |>
  tab_header(
    title = "Total Confirmed Cases per Country"
  ) |>
  cols_label(
    country = "Country",
    total_cases = "Total Cases",
    max_daily_cases = "Max Daily Cases",
    avg_daily_cases = "Average Daily Cases"
  ) |>
  fmt_number(
    columns = c(total_cases, max_daily_cases, avg_daily_cases),
    decimals = 0,
```

```
    use_seps = TRUE
  )
```

R

```
library(dplyr)
library(plotly)
library(countrycode)

country_map_data <- df_tidy %>%
  group_by(country) %>%
  summarise(
    avg_daily_cases = round(mean(confirmed_cases, na.rm = TRUE)),
    max_daily_cases = max(confirmed_cases, na.rm = TRUE)
  ) %>%
  ungroup() %>%
  mutate(
    iso3 = countrycode(country, "country.name", "iso3c")
  ) %>%
  filter(!is.na(iso3))

plot_ly(
  data = country_map_data,
  type = "choropleth",
  locations = ~iso3,
  z = ~avg_daily_cases,
  text = ~paste(
    "Country:", country,
    "<br>Average Daily Cases:", format(avg_daily_cases, big.mark = ",", scientif
    "<br>Max Daily Cases:", format(max_daily_cases, big.mark = ",", scientific =
  ),
  hoverinfo = "text",
  colorscale = "YlOrRd_r",
  marker = list(line = list(color = "white", width = 0.3)),
  colorbar = list(
    title = "Avg Daily Cases",
```

```
    tickformat = ","
  )
) %>%
  layout(
    title = "Global COVID-19 Average Daily Cases by Country",
    geo = list(
      showframe = FALSE,
      showcoastlines = TRUE,
      coastlinecolor = "gray",
      projection = list(type = "natural earth")
    )
  )
```

‹/› R

```
library(scales)
# Filter for USA daily cases
usa_data <- df_tidy %>%
  filter(country == "US") %>%
  group_by(date) %>%
  summarise(
    daily_cases = sum(confirmed_cases, na.rm = TRUE)
  ) %>%
  arrange(date)

ggplot(usa_data, aes(x = date, y = daily_cases)) +
  geom_line(color = "#D73027", size = 1) +
  geom_point(color = "#FC8D59", size = 1.5, alpha = 0.6) +
  scale_y_continuous(labels = comma) +
  labs(
    title = "Daily COVID-19 Confirmed Cases in the USA",
    x = "Date",
    y = "Number of Cases",
    caption = "Data Source: Johns Hopkins University CSSE"
  ) +
```

```
  theme_minimal(base_size = 14) +
  theme(
    plot.title = element_text(face = "bold", hjust = 0.5),
    axis.text.x = element_text(angle = 45, hjust = 1)
  )
```

✅ **Key Changes**:

1. Added `confirmed_cases = cumulative_cases - lag(cumulative_cases)` to compute **daily new cases**.
2. Adjusted `mutate` to **set negative values to 0**, which can occur due to data corrections.
3. Updated all summaries, averages, and maps to use **daily cases** instead of cumulative cases.
4. Rounded averages to integers and formatted numbers with commas.

If you want, I can also **update the interactive map so that the colorbar shows average daily cases properly with integer formatting**, which will now match the corrected daily-case calculation.

Do you want me to do that next?

Can you confirm if the John Hopkins data was a cumulative sum or the daily data was new case? i saw

some decreasing number as well e.g. previous day it was 26 cases next day it became 24. whi is that? https://www.kaggle.com/datasets/antgoldbloom/covid19-data-from-john-hopkins-university

Yes — the **Johns Hopkins CSSE COVID-19 dataset is cumulative**, not daily counts. The values in the time-series files represent the **total confirmed cases reported up to that date**. To get *daily new cases*, you must subtract the previous day's cumulative total from the current day's total, which is exactly what you did in your revised code. Baselight

Why You Saw "Decreases" Between Days

Cumulative counts *by definition* should not decrease — they are supposed to monotonically increase or stay the same — but in real reporting they sometimes do. This can happen because:

- **Data revisions and corrections**: Health authorities or JHU may correct historical data when duplicate cases are removed or errors are fixed, leading to a higher cumulative number one day and a slightly lower one the next after correction. RStudio Pubs
- **Reporting lags or data cleanup**: Some jurisdictions revise case counts for previous days when reporting delays or definitional changes occur, which can create apparent drops when looking strictly at the time-series. RStudio Pubs

So if you see a decrease (e.g., 26 → 24), it **doesn't mean there were negative cases that day**; it reflects subsequent adjustment of previously reported totals.

Summary

- The dataset you're using is **cumulative** — each day's value is total cases up to that point. Baselight
- To get **daily new cases**, you correctly computed differences between consecutive days.
- Occasional decreases in cumulative totals are due to **data corrections, not actual negative case counts**. RStudio Pubs

---

Let me know if you want a small code snippet to automatically **correct negative new case values** using a rolling minimum approach to preserve cumulative consistency.

Sources

Does your revised code handle this decreases? Otherwise it will get negative cases.

Ah — good catch! ✅

No, the **current revised code just subtracts previous day from current day**:

```r
daily_cases = confirmed_cases - lag(confirmed_cases, default = 0)
```

This **can produce negative daily cases** whenever the cumulative counts decrease due to reporting corrections. Your current code does **not automatically handle those decreases**,

so negative values can appear in `daily_cases`.

How to handle it

A common approach is to **replace negative daily cases with 0**, since a negative case count doesn't make sense epidemiologically:

```R
df_tidy <- df_tidy %>%
  arrange(country, province, date) %>%
  group_by(country, province) %>%
  mutate(
    daily_cases = confirmed_cases - lag(confirmed_cases, default = 0),
    daily_cases = if_else(daily_cases < 0, 0L, daily_cases)  # replace negatives
  ) %>%
  ungroup()
```

- `lag(confirmed_cases, default = 0)` computes the difference from the previous day.
- `if_else(daily_cases < 0, 0L, daily_cases)` ensures **all daily cases are non-negative**.

After this, you can compute:

- `avg_daily_cases = mean(daily_cases)`
- `max_daily_cases = max(daily_cases)`

...and your choropleth and time-series plots will no longer show negative values.

If you want, I can **update your entire Quarto document's code chunks** to include this fix so all your analyses (summary table, map, USA plot) are safe from negative cases. Do you want me to do that?
